

CMS Strip Readout Architecture for SLHC

OUTLINE

- brief review of LHC strip readout architecture
- proposed architecture for SLHC
- front end amplifier design in 130nm
- system architecture ideas
- triggering possibilities with strips
- summary

Mark Raymond – Imperial College London

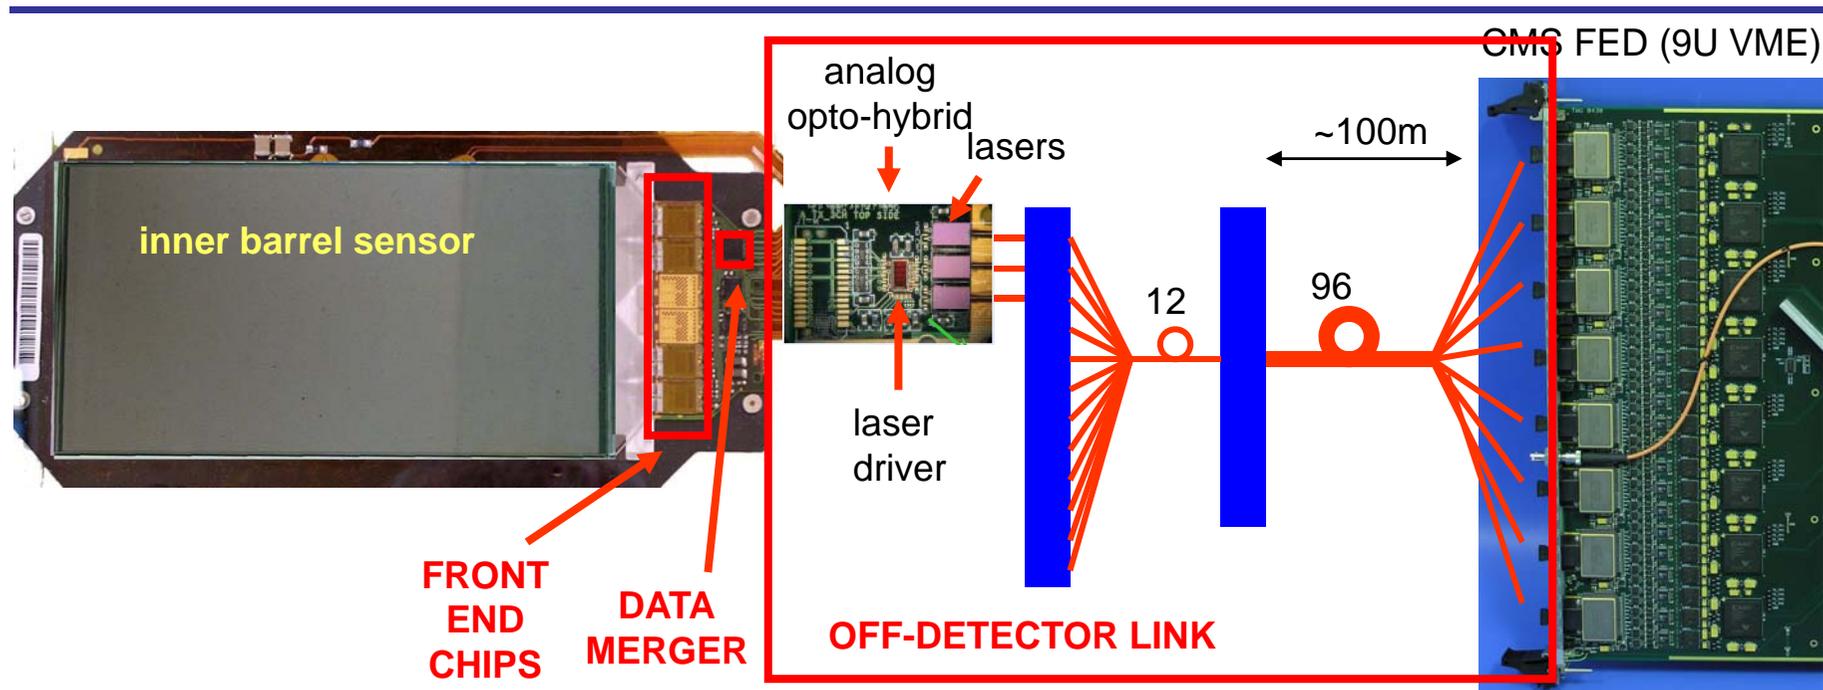

CMS LHC Si strip readout system

analogue readout

- APV25 0.25 μm CMOS FE chip
- APV outputs analog samples @ 20 Ms/s
- APVMUX multiplexes 2 APVs onto 1 line @ 40 MHz
- Laser Driver modulates laser current to drive optical link @ 40 Ms/s / fibre
- O/E conversion on FED and digitization @ ~ 9 bits (effective)

CMS LHC strip readout system

LHC strip readout system actually rather simple – breaks down into 3 components

FRONT END CHIPS

APV25

DATA MERGER

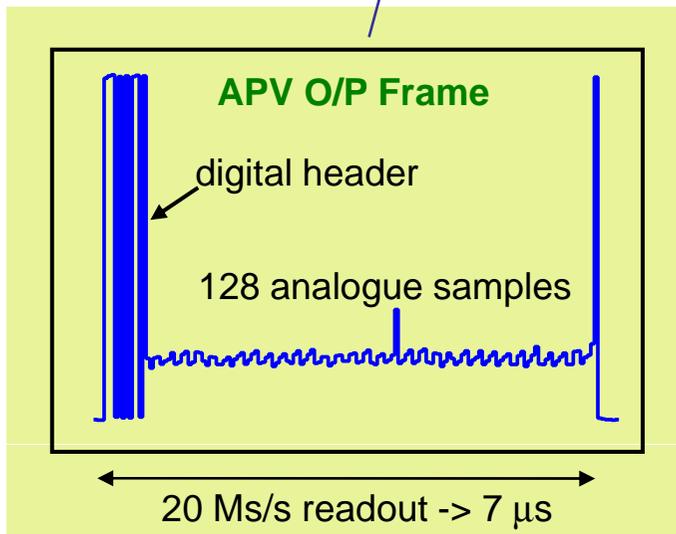

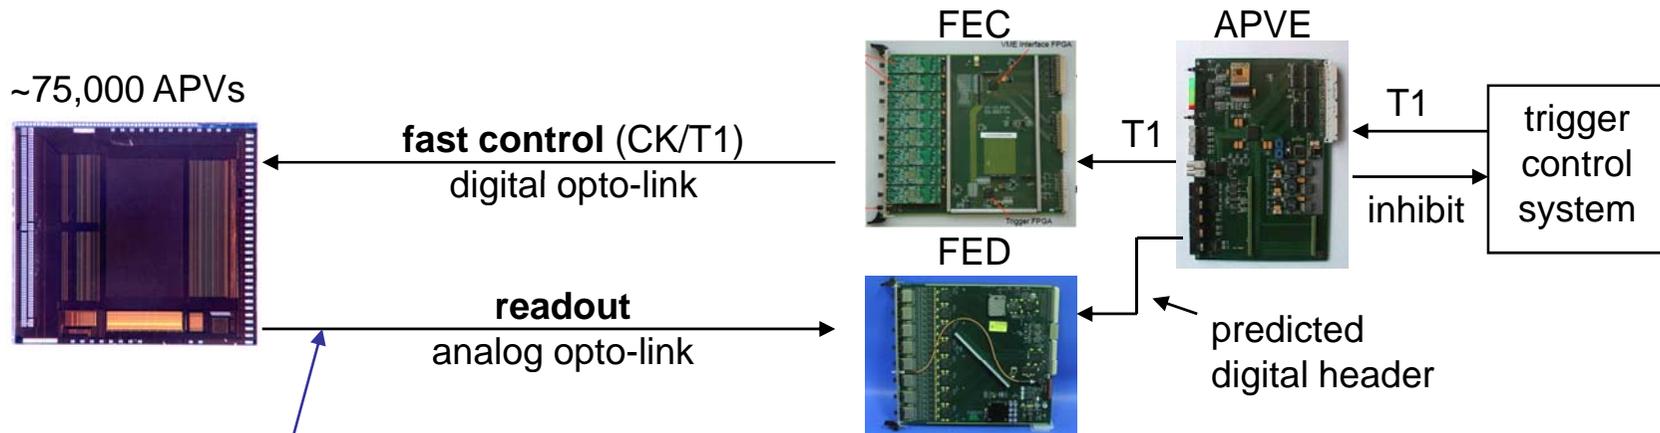

APVmux – multiplexes outputs of 2 APVs onto one line

OFF-DETECTOR LINK

analogue – APVmux output drives laser driver => 2 APVs per off-detector fibre

system simplicity comes from choosing not to zero-suppress (sparsify) on front end

LHC control / readout chain overview

no zero-suppression (sparsification) on detector

all 75,000 APVs operating synchronously
(all FE chips doing same thing at same time)

advantages

- can be emulated externally (APVE) to prevent APV buffer overflows
- no need to timestamp on front end
- data volume occupancy independent
- easy to identify upset chips (digital header)

pedestal, CM subtraction and zero suppression on FED
raw data also available for setup, performance monitoring
and fault diagnosis

analog, unsparsified readout provides relatively simple and robust system

SLHC challenges for CMS tracker

1) power

higher granularity => more FE chips
electronics related material dominates existing material budget
(cabling, cooling) & we want to reduce this

2) triggering

not possible to keep L1 trigger rate at 100 kHz without
contribution from tracker

=> **new features and existing architectures need re-design
and replacement**

what we like about our present system

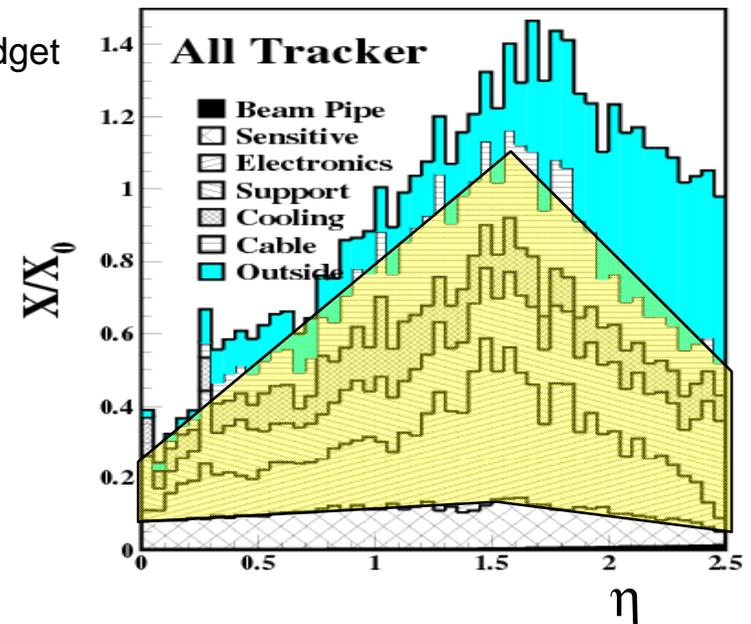

analog pulse height info
made possible by custom analog off-detector link
no on-detector sparsification
system simplicity - no fluctuating data volumes event-to-event

what must change for SLHC

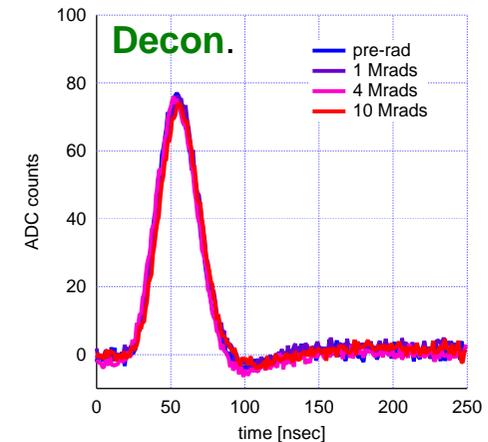

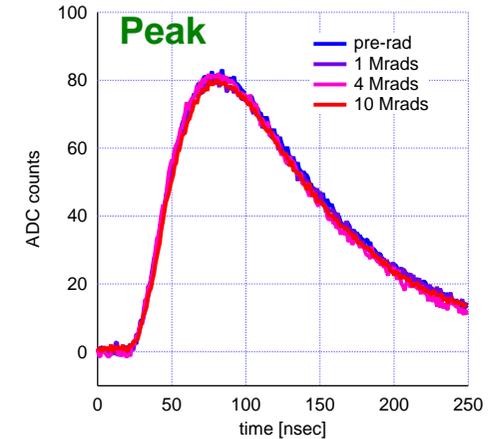

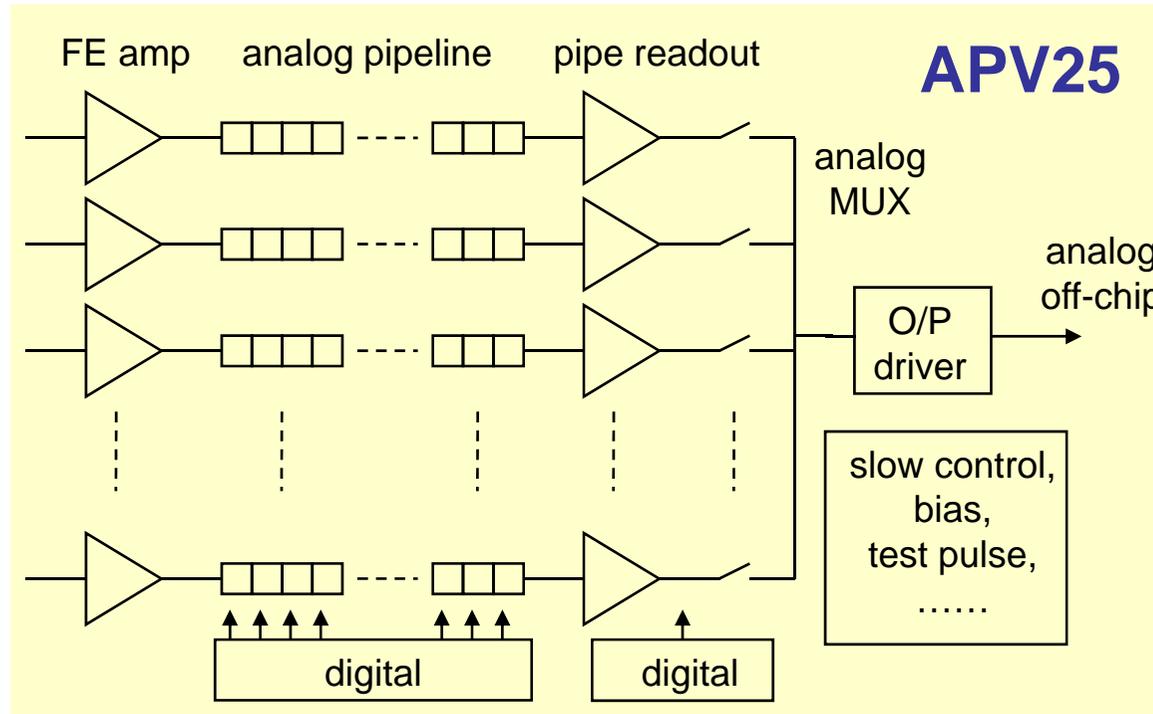

off-detector links -> high speed digital
=> digitization on FE if want to retain pulse height info

will look at pros and cons of different FE chip architectures

CMS tracker material budget

LHC front end chip architecture

existing LHC architecture – APV25

slow 50 nsec CR-RC FE amplifier, analog pipeline, 2.7 mW/channel

peak/deconvolution pipe readout modes

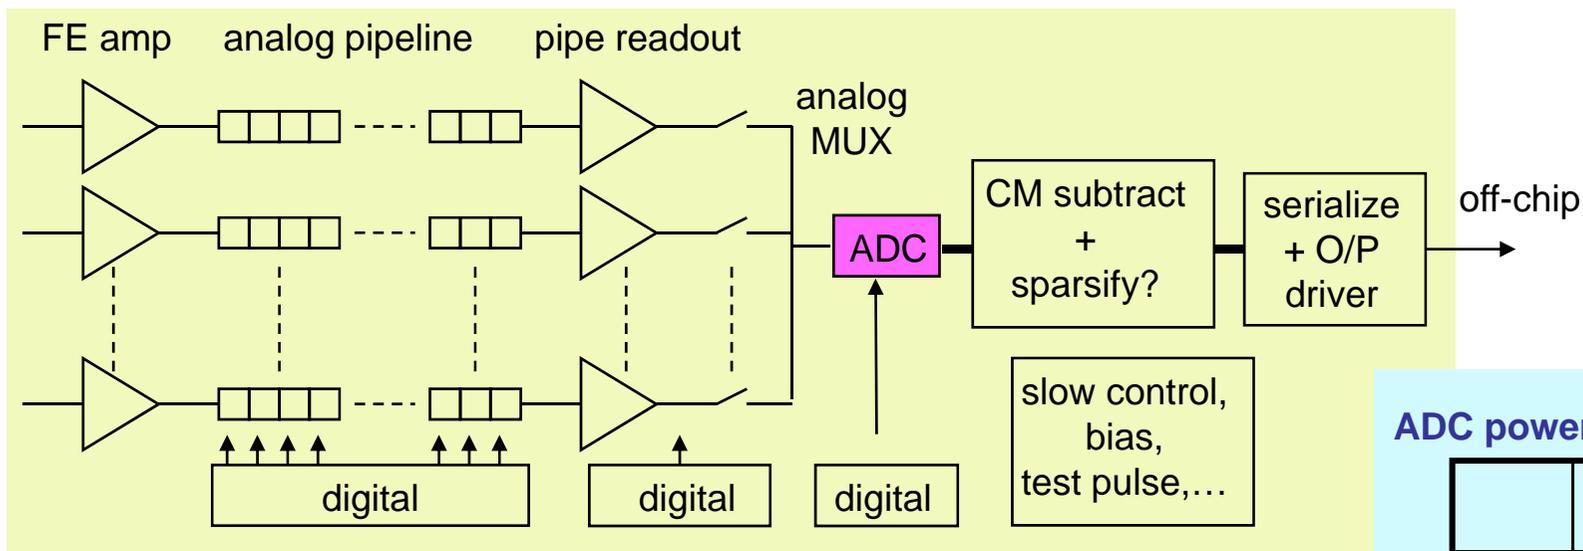

peak mode -> 1 sample -> normal CR-RC pulse shape

deconvolution -> weighted sum of 3 consecutive samples combined to give single BX resolution

all analog approach – not compatible with digital off-detector data transmission

moving to SLHC – if want to retain pulse height information – where to digitise?

“digital APV” architecture

ADC power @ 20 MHz [mW]

	130nm	65nm
8 bits	6.4	2.5
6 bits	1.6	0.6

from ITRS roadmap 2003

digitization before pipeline? (on every channel)

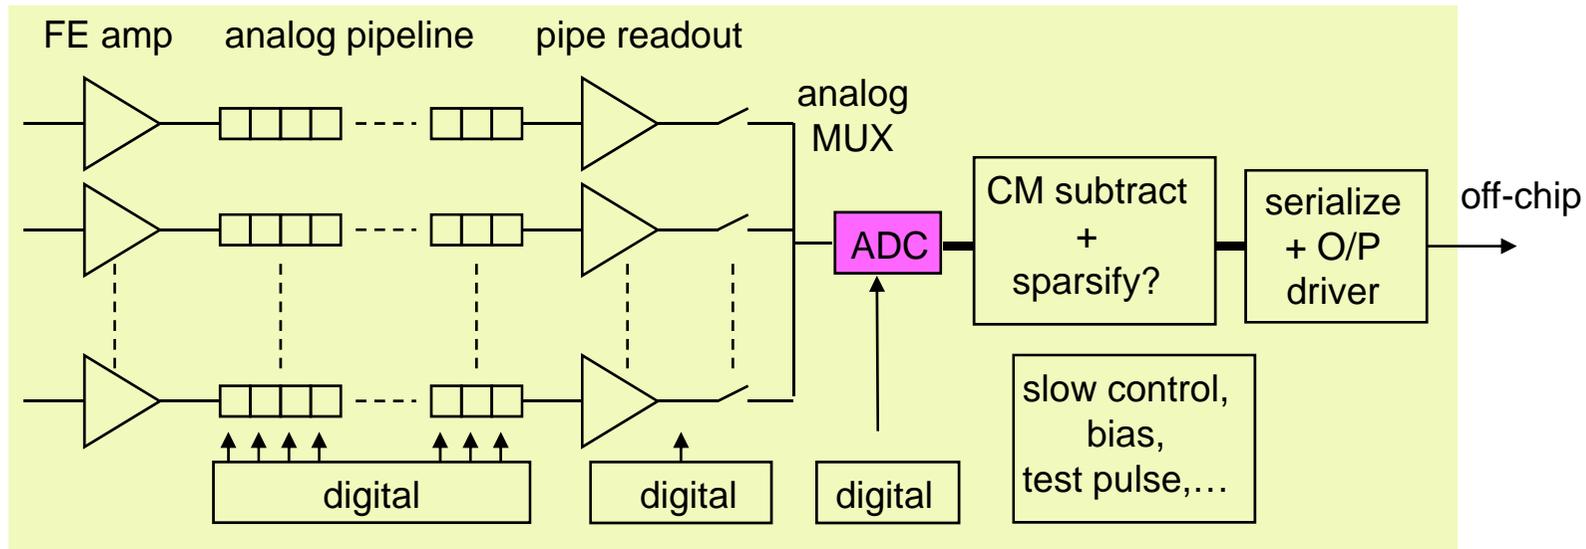

early assumptions said no – ADC power too high (ITRS 2003)
 still valid? - maybe not in future processes (90 nm, 65 nm)
 some new ADC architectures beating previous power predictions *
 but negligible power / channel still some way off

digitization after pipeline?

negligible power/channel **is** achievable - ADC power shared between all front end channels
 analog pipeline remains so could retain slow shaping + analog deconvolution approach

but this architecture still brings some disadvantages

digital APV architecture disadvantages

very complicated chip – all the complexity of APV + more

fast ADC required

data volume means sparsification necessary to keep data at manageable levels

on-chip CM subtraction probably necessary (analogue pipeline contributes)

off-detector
FED features in
existing system

analogue pipeline using gate capacitance may still be possible in 130nm – not in finer processes

(plan to increase pipeline length for SLHC)

analogue circuitry throughout chip – harder to achieve supply noise rejection

sparsification leads to on-detector system complexity

extra buffering required (more chips) to cope with varying trigger-to-trigger data volume

front-end timestamping

if want to keep simple un-sparsified system => pulse ht. info has to go => binary

binary architecture – un-sparsified

what about binary un-sparsified?

much simpler (than digital APV)
particularly for pipeline and readout side

need fast front end and comparator
=> more power here

but no ADC power and much simpler digital
functionality will consume less – this
architecture **will** be lowest power

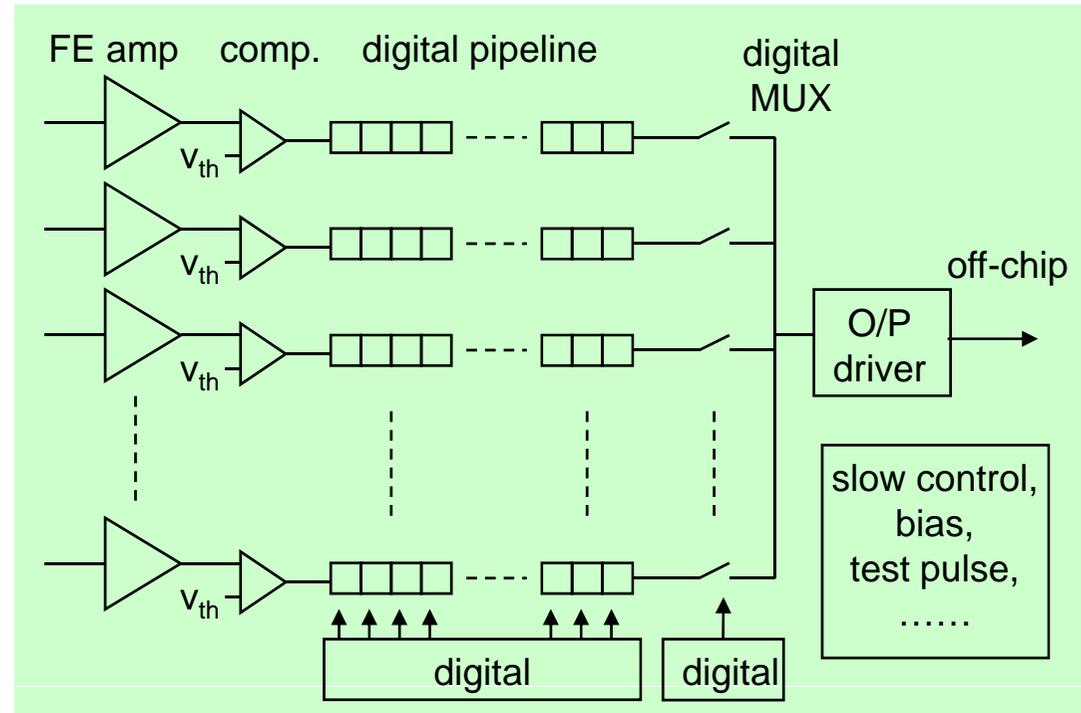

binary architecture also compatible with
some approaches to track triggering layers

can retain system features we like

simpler synchronous system, no FE timestamping
data volume known, occupancy independent (no trigger-to-trigger variation)

un-sparsified binary is the option we are currently planning to implement

but less diagnostics (can measure front end pulse shape on every channel in present system)
loss of position resolution
common mode immunity

front end amplifier design

binary FE design has begun in 130 nm CMOS

preliminary specifications and assumptions

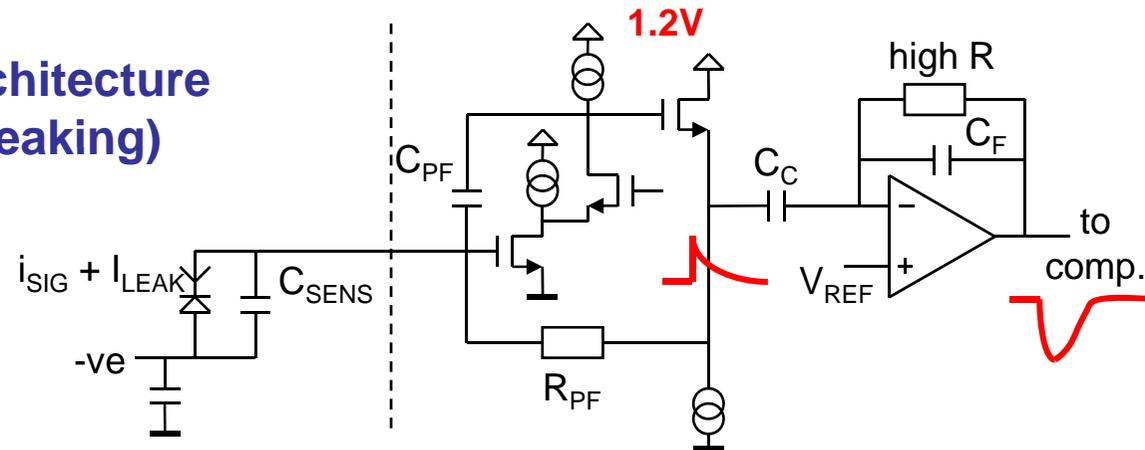

n-on-p sensor (signal current flows out of amplifier)
promising option for rad hard sensors

need to tolerate leakage current up to $\sim 1 \mu\text{A}$
allows DC coupling for lower cost sensors

need to be fast enough for acceptable timewalk
aim for peaking time $\sim 20 \text{ nsec}$

130nm front end amplifier

current preferred architecture
for fast FE (~20 ns peaking)

Preamp

NMOS I/P device

- no noise penalty - $1/f$ corner low enough (simulation & published measurements)
- better connection to sensor for PSR (sensor bias decoupling and I/P FET source both at GND)

real resistor feedback

- low R_{pf} (200k) allows DC leakage to be accommodated ($1 \mu\text{A} \rightarrow 200 \text{ mV}$)
- uses highest resistance technology in process (1k7/square poly, +/-20%)
- $R_{pf} // C_{pf} = 200\text{k} // 100\text{fF} = 20 \text{ ns}$ decay time constant of preamp (no pile-up)
- 200k contributes $\sim 220e$

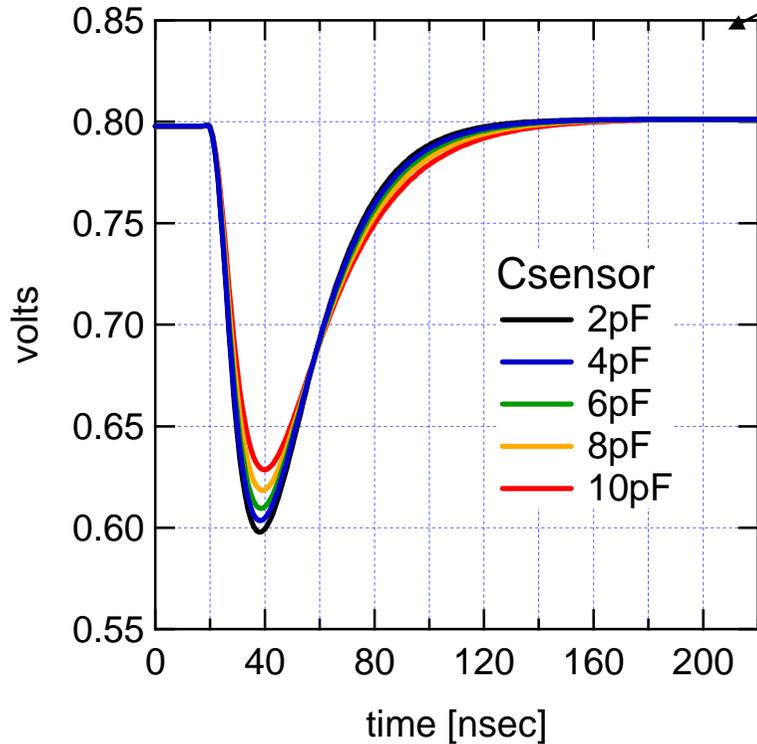

Postamp

- provides gain & risetime provides integrating time constant
- AC coupled to preamp (DC shift due to leakage decoupled)
- O/P DC level set by V_{REF} – defines DC level at output (comparator input)

will show some simulated performance pictures – all results at preliminary stage

binary FE pulse shape and noise

pulse shapes for 4 fC input charge
(~ 45 mV / fC)

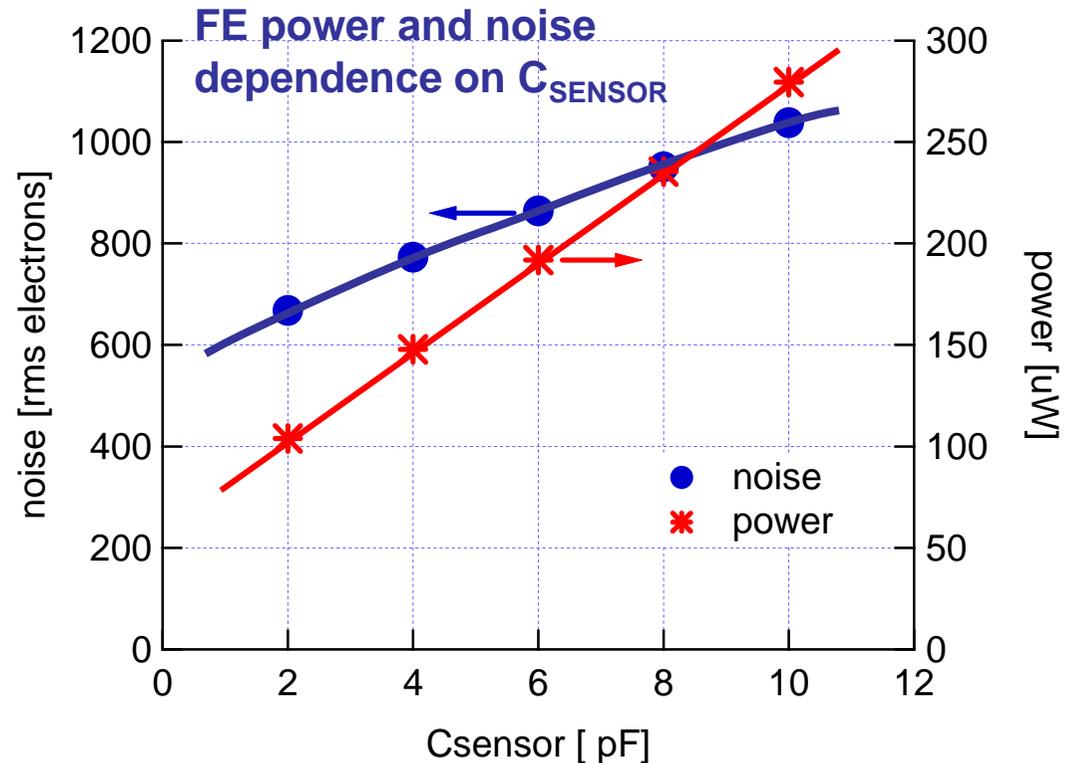

pulse shape tuned to keep peaking time ~ constant as C_{SENSOR} varies by increasing current in input FET (I_{DS})

preamp risetime $\propto C_{\text{SENSOR}}/g_m$ ($\propto C_{\text{SENSOR}}/I_{\text{DS}}$)

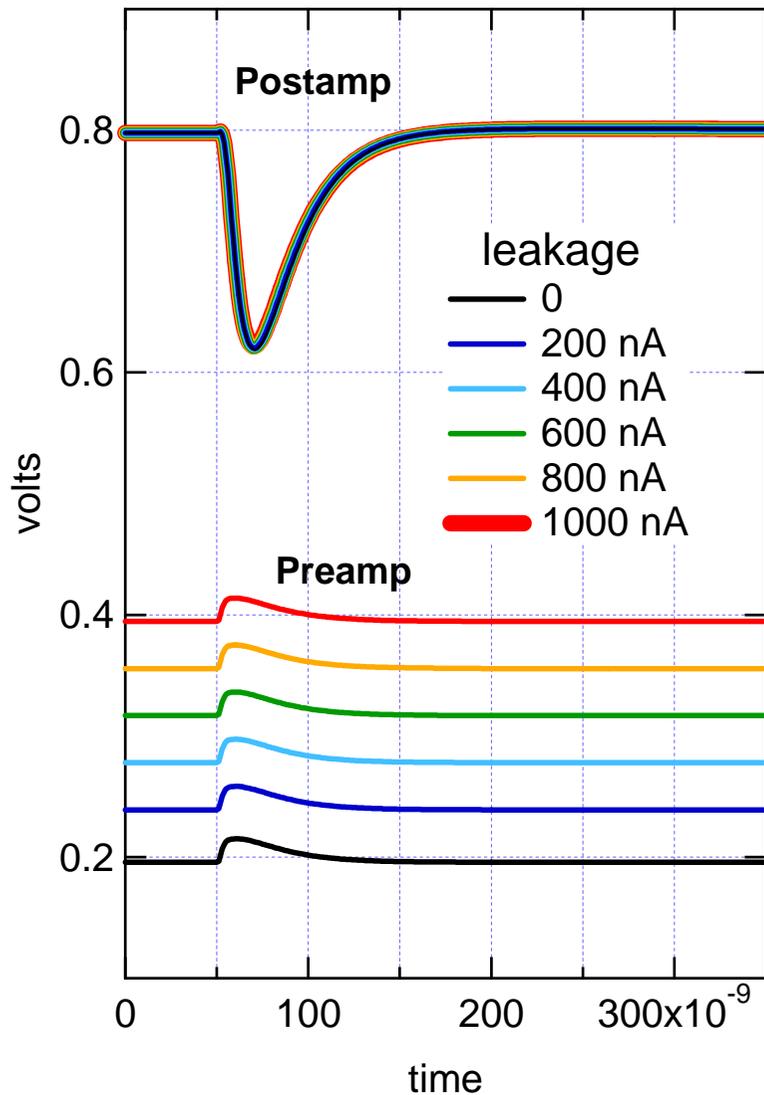

=> power scales linearly with C_{SENSOR}

noise < ~900e for power ~ 200 μW for $C_{\text{SENSOR}} \sim 6$ pF

always a trade-off between power and noise
e.g. thin sensors (< 4fC/mip) or long strips will
need more power to achieve acceptable S/N

Effects of leakage current

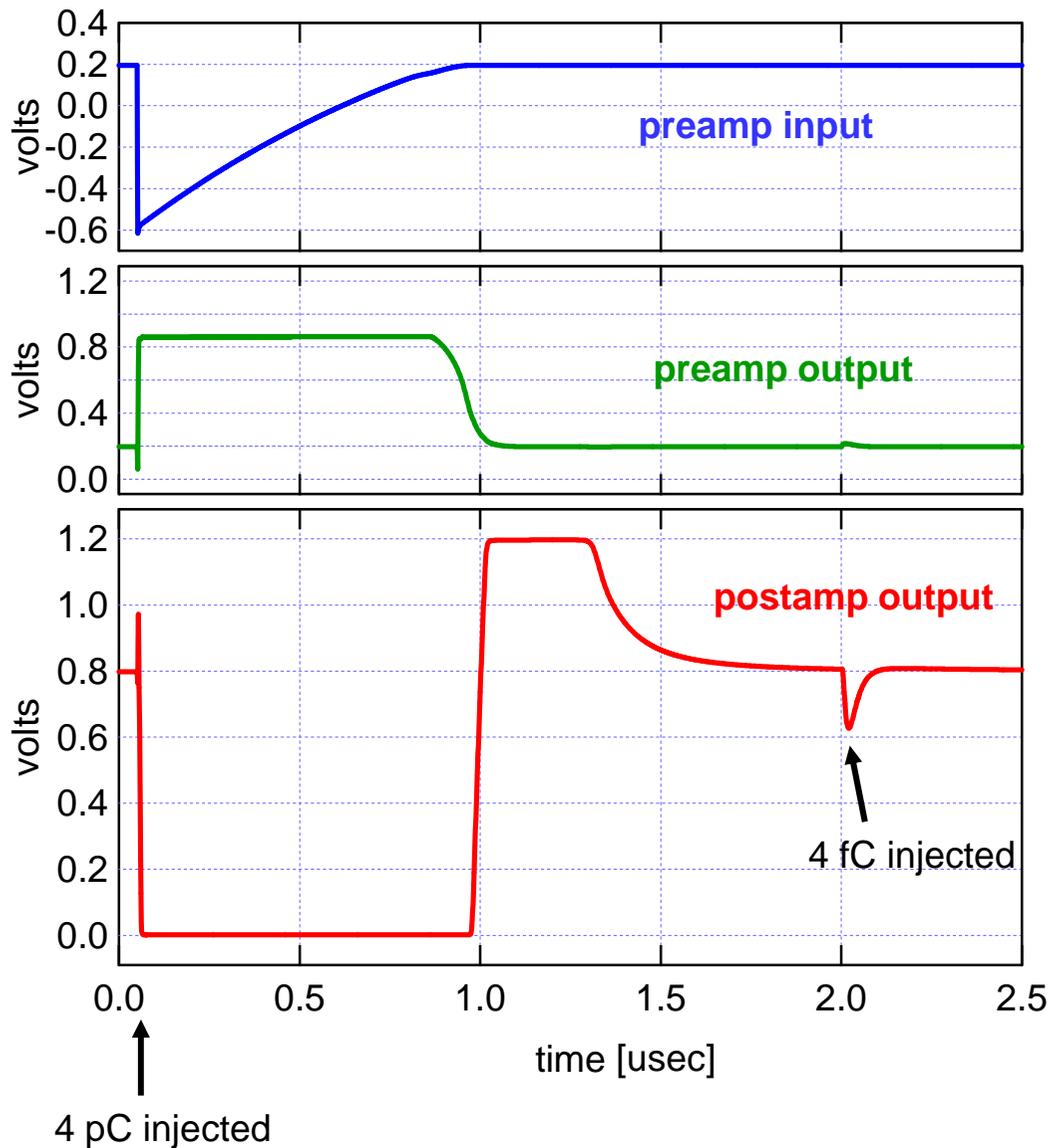

postamp output unaffected (AC coupled)

preamp output shows DC shift across R_{PF}

1 μA leakage contributes $\sim 440e$ noise to be added in quadrature to amplifier noise (short shaping time helps with parallel noise)

e.g. 900 (total amplifier for $C_{\text{SENSOR}} \sim 6 \text{ pF}$)
+ 440 (leakage)
= $\sim 1000e$ total

response to overload

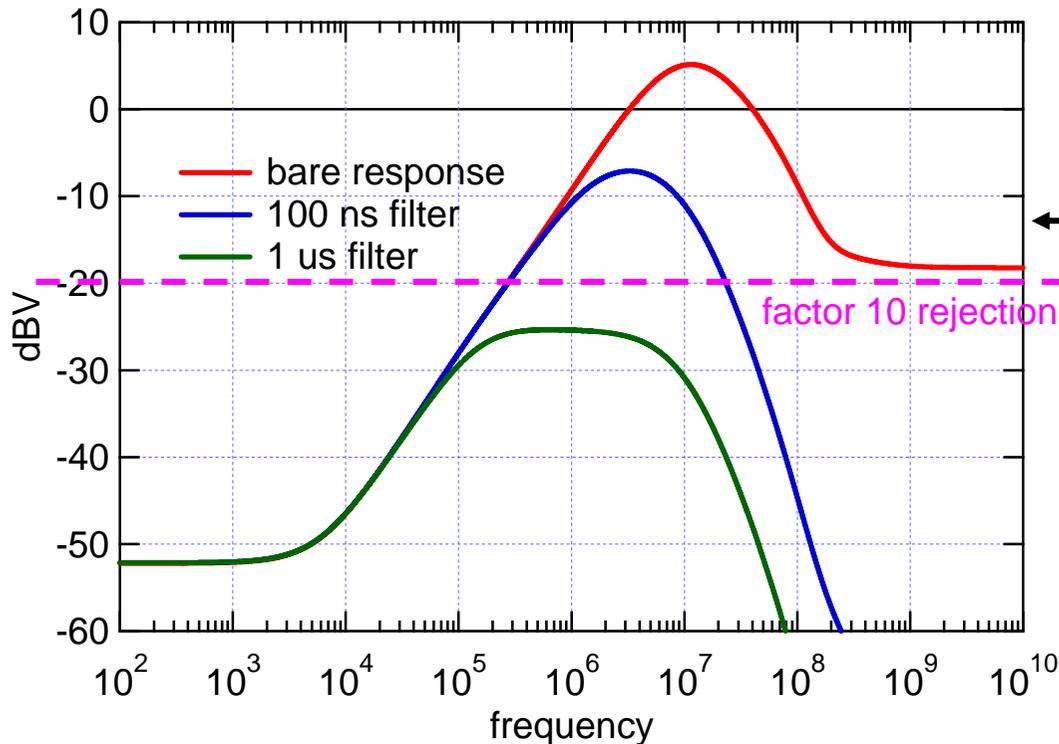

overload behaviour well-controlled

low R_{PF} beneficial

front end recovers from 4 pC signal and sensitive to normal signals within 2.5 μ s

=> no "APV-like" hips effect

power supply rejection

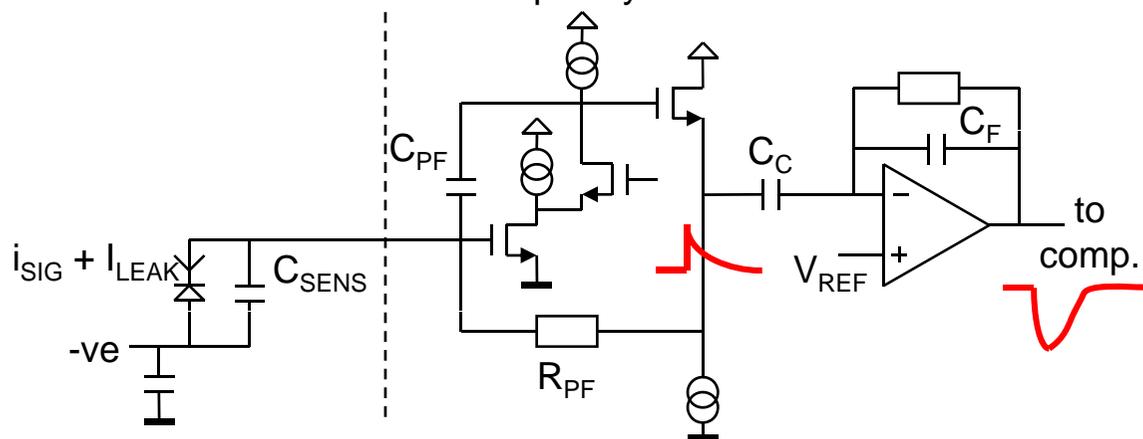

baseline choice for CMS tracker powering is parallel powering (DC-DC) so PSR will be an issue

← power supply rejection at postamp output to sinusoidal waveform on positive supply rail

bare response shows good rejection at low frequency, peaking at ~10 MHz

AC preamp/postamp coupling together with opamp postamp gives good low f behaviour

peaking at ~10 MHz (gain) due to coupling through bias circuits

can improve with realistic filtering, but would prefer some rejection at all frequencies to start with

needs further study

power estimate

130nm binary chip – non-sparsified readout

0.5 mW / channel seems like an achievable target (c.f. 2.7 mW for APV25)

	power / channel
preamp/postamp e.g. 20 nsec peaking time, short strips $C_{\text{SENSOR}} \sim 5\text{pF}$	180 μW
comparator estimate from preliminary simulations	20 μW
miscellaneous digital estimate loosely based on APV pipe and control logic	60 μW
mux + output driver + just guess nominal figure to bring overall power to 0.5 mW will depend on implementation. e.g. choice of electrical protocol can hope for saving here, but good to have contingency	240 μW

digital is biggest uncertainty, and maybe largest contributor
can consider running at lower voltage (dig. power $\sim V^2$)
should keep power rails separate on chip to keep option open

full prototype in 1st iteration

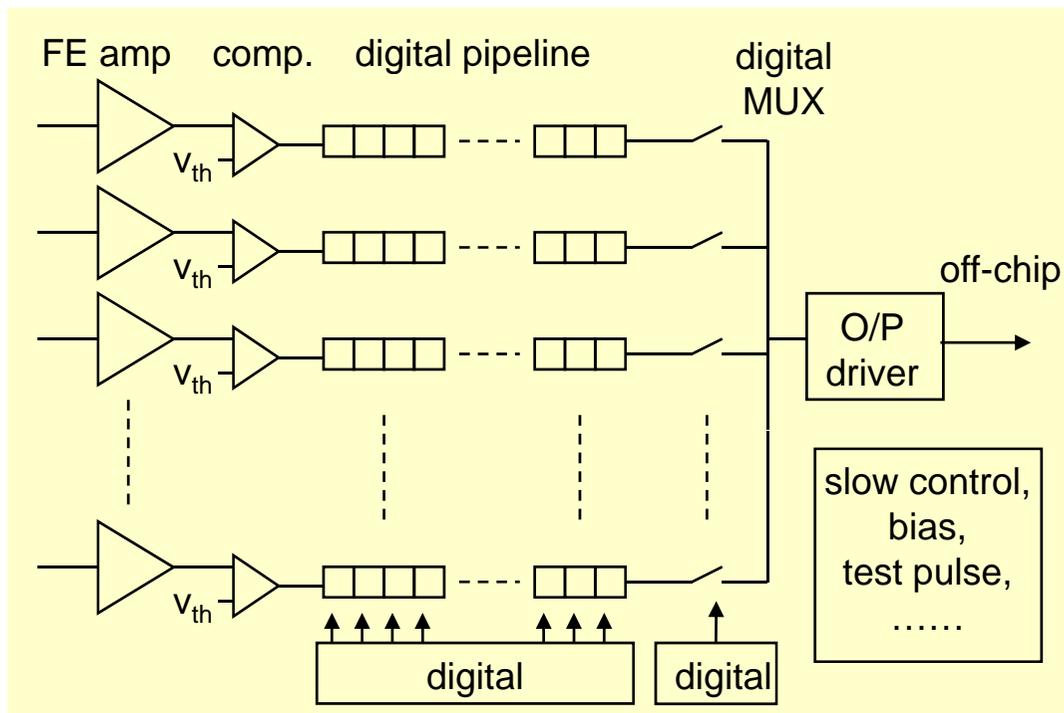

relative simplicity of unsparsified binary architecture means can go for complete chip on timescale ~ 1year
less risky than complex “digital APV”

will learn a lot sooner rather than later

will also provide collaborators with something to use to evaluate sensors and modules

choose front end most likely to suit SLHC (e.g. n-side readout?)
(can still submit test structures for alternative front ends)

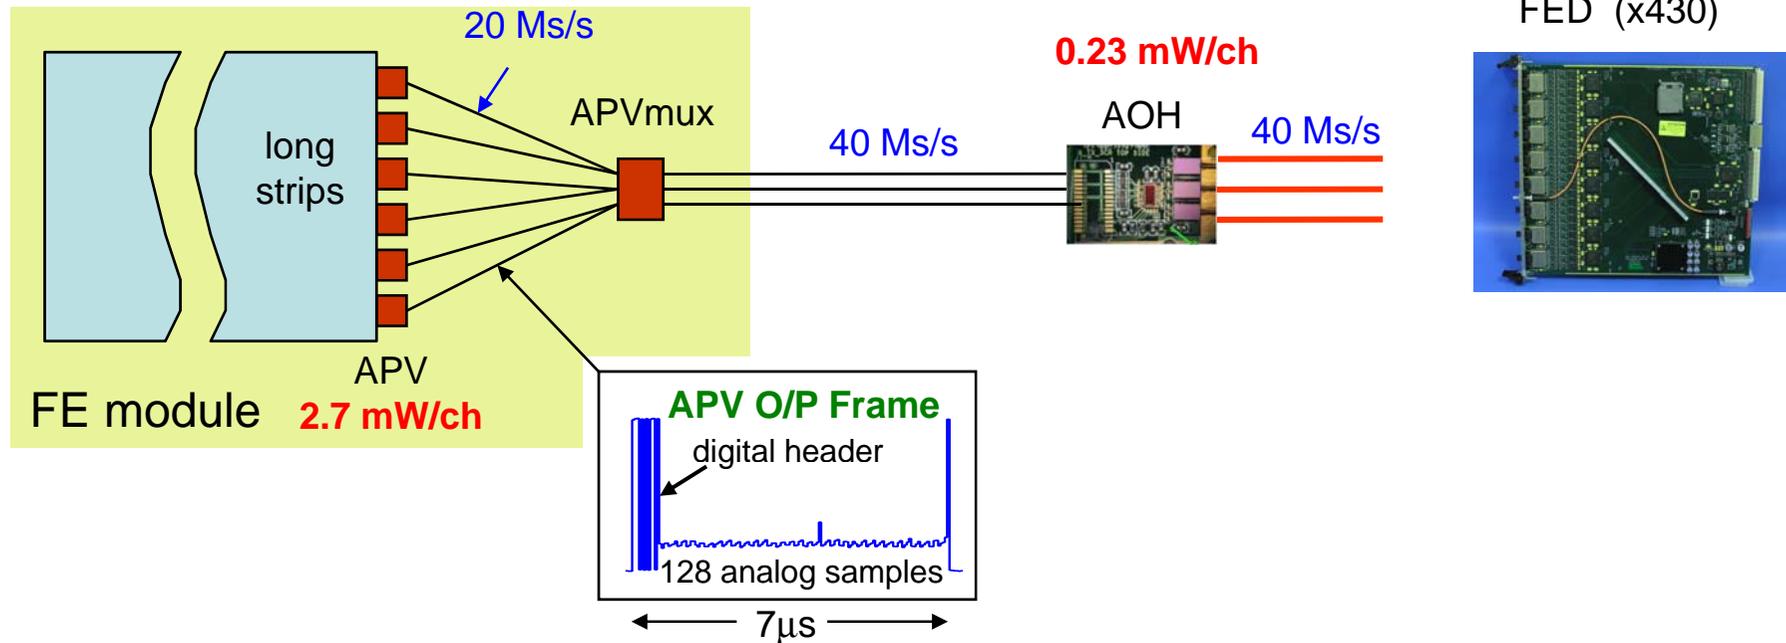

CBC (CMS Binary Chip)

may leave out some features
e.g. bias gen., test pulse, I²C I/F

but should have main functionality:
pipeline, pipe control logic, and mux.,
trimDAC for comparator thresholds,

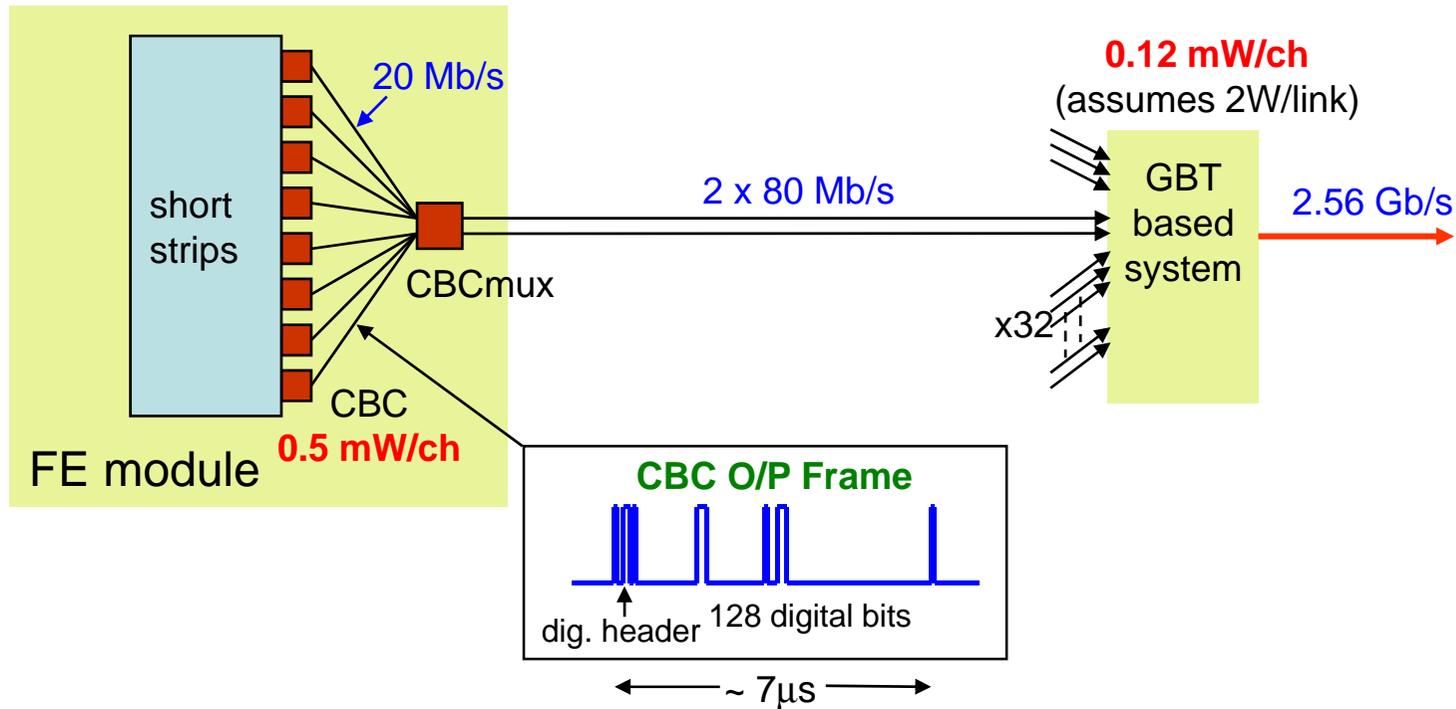

LHC -> SLHC strips readout system

recap LHC

APV provides analogue unsparsified output data at 20 Ms/s
data frame 7 μs => 70% of off-detector bandwidth used for 100 kHz trigger
2 APVs data interleaved at 40 Ms/s on one electrical line (differential)
one-to-one correspondence to off-detector fibre (i.e. still 2 APVs / fibre)
link power <10% overall channel power

LHC -> SLHC strips readout system

moving to SLHC - early ideas

binary unsparsified, but output frame format can be similar to APV (just hits, not analog values)

CBC could provide output data at **20 Mb/s**

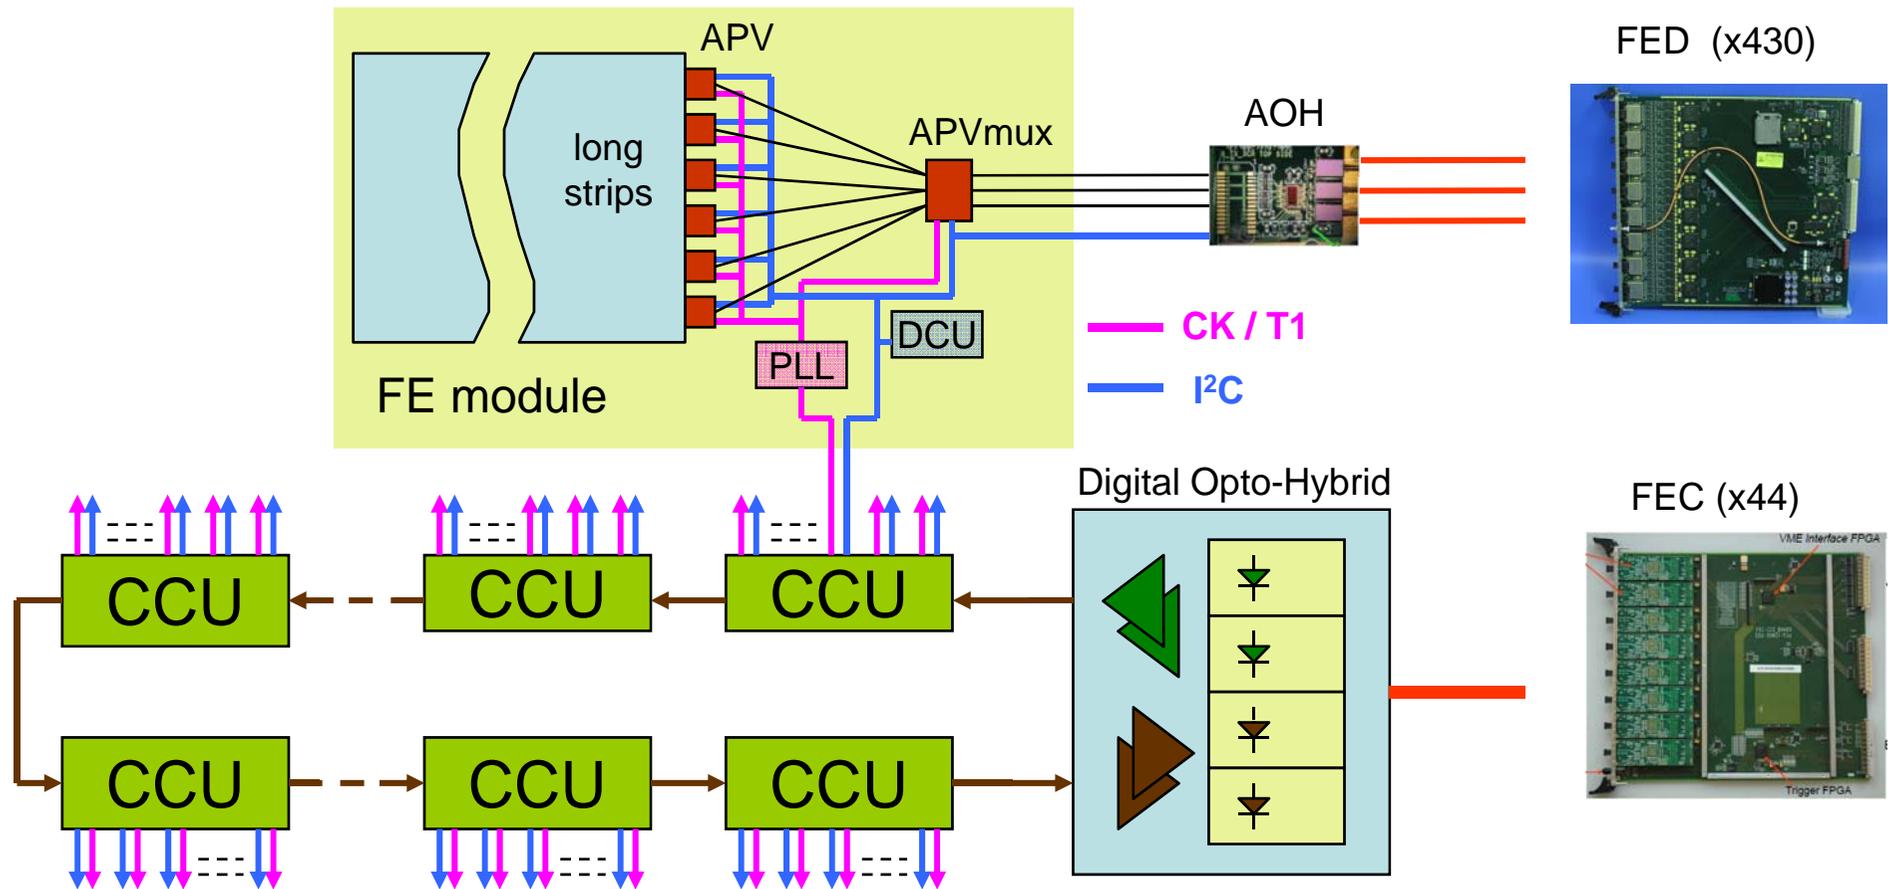

keep data frame **~7 μs**

=>4 CBCs data multiplexed at **80 Mb/s** onto one electrical line (GBT lane)

32 x 80 Mb/s lanes combined on **2.56 Gb/s** off-detector fibre (128 CBCs / fibre)

link power ~ 20% overall channel power (assumes 2W / link)

LHC strips readout & control system

CCU distributes **CK/T1** and **I²C** control busses to up to 16 FE modules

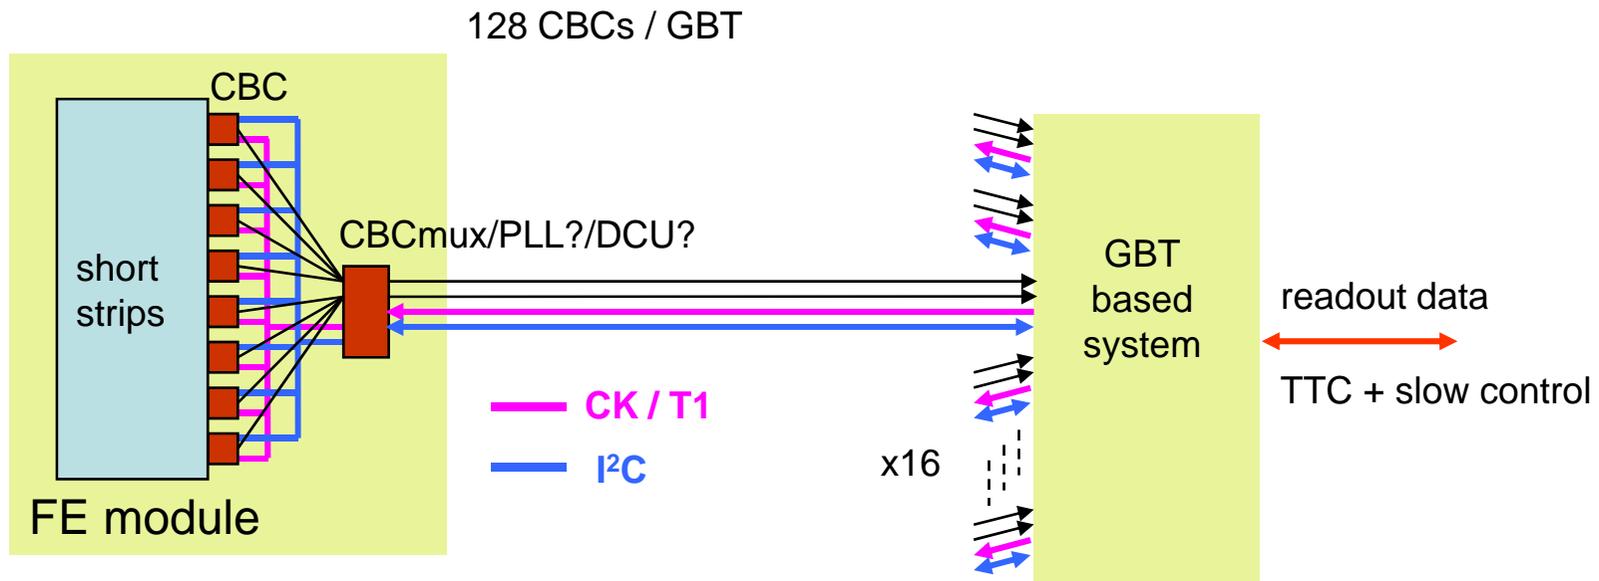

PLL chip recovers **CK** and **T1** (missing clock pulse) on FE module

DCU chip monitors FE currents, voltages and temperatures

I²C used for programming APVs, reading DCU monitoring info, setting up AOH

CCU chip electrical control ring architecture on front end reduces no. of control fibres required

SLHC strips readout & control system

system design here is not yet well defined (my thoughts here)

should be much simpler (on-detector) than LHC system
e.g. could combine mux/PLL/DCU functionalities in one chip?

GBT based system means GBT + whatever else is needed (if anything)
does this map to current GBT functionality?

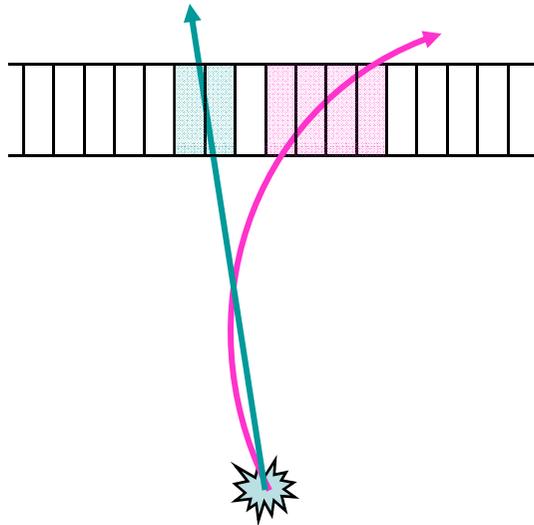

I²C and CK/T1 could be common to a number of FE modules

track triggering

two concepts compatible with microstrip tracker

W.Erdmann
R.Horisberger *

Cluster Width Discrimination

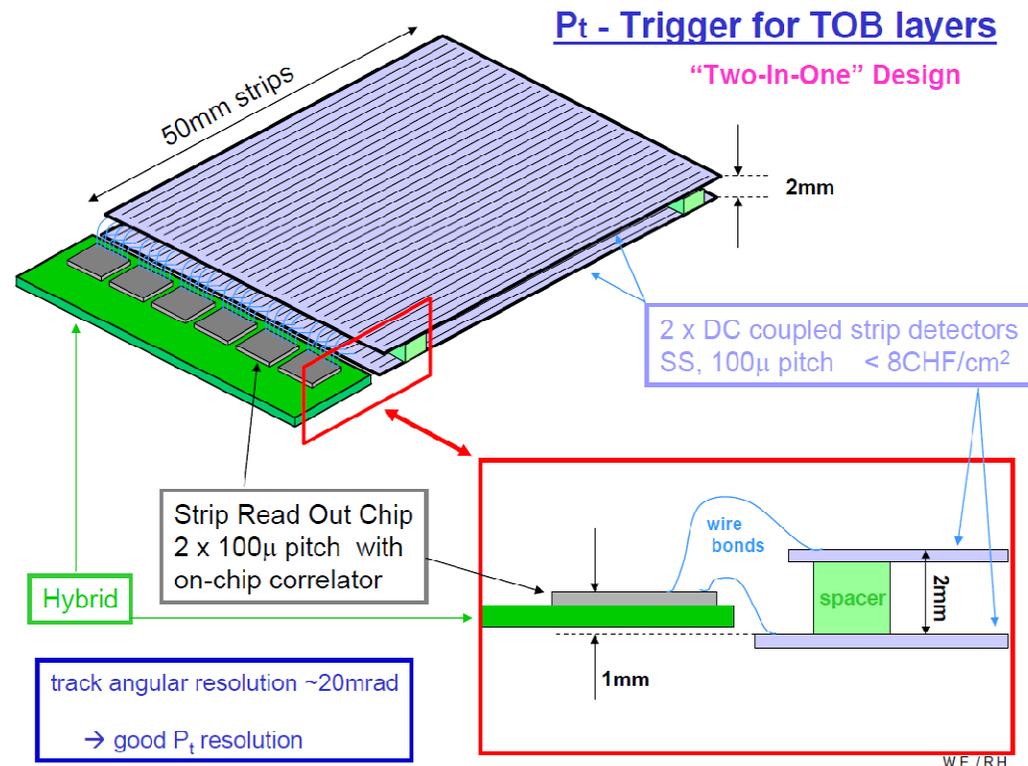

high P_T track \rightarrow narrow cluster width

see: Track momentum discrimination using cluster width in Si strip sensors, *G.Barbagli, F.Palla, G. Parrini, TWEPP07*

Two-In-One Design

bond stacked upper and lower sensor channels to adjacent channels on same ASIC
no interlayer communication - no extra correlation chip
just simple logic on readout chip, looking at hits (from 2 layers) on adjacent channels

Hybrid

Strip Read Out Chip
2 x 100µ pitch with
on-chip correlator

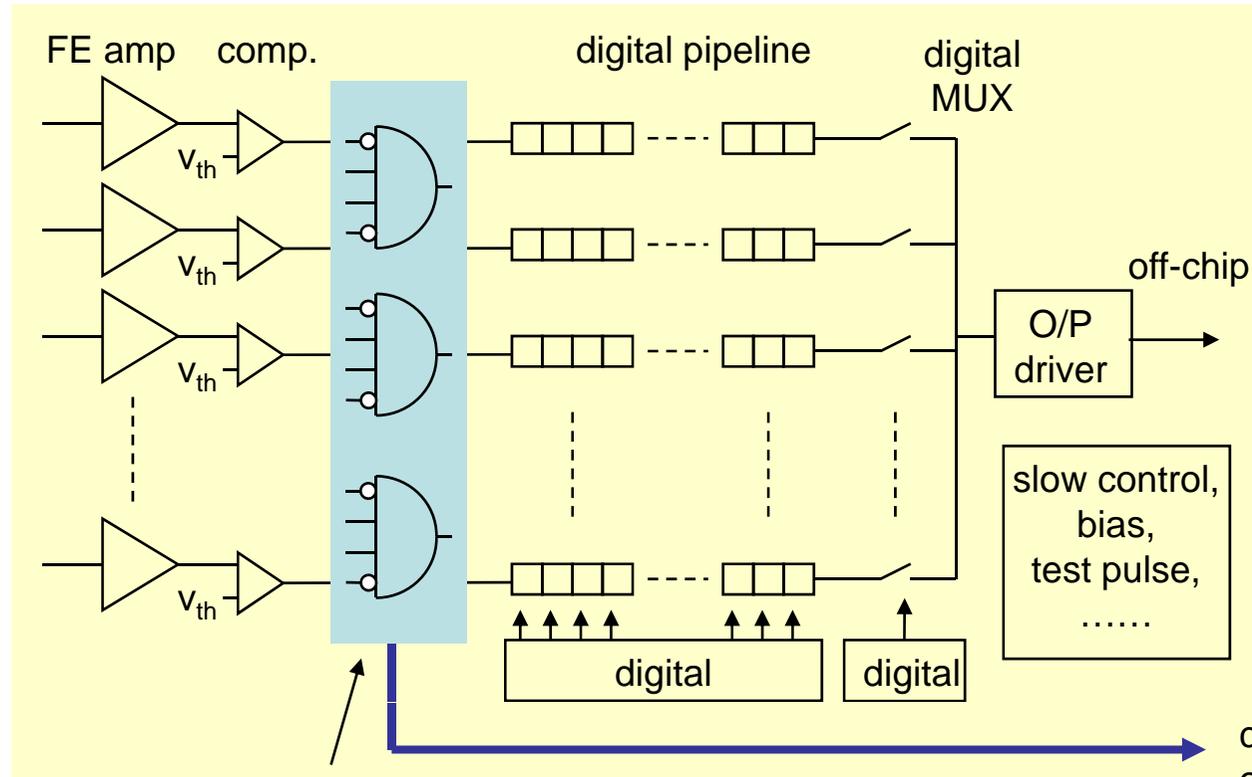

track angular resolution $\sim 20\text{mrad}$
 \rightarrow good P_T resolution

2 x DC coupled strip detectors
SS, 100µ pitch < 8CHF/cm²

WE/RH.

triggering logic on FE chip

simple logic to select cluster width (programmable)
(or coincidence window between layers for 2-in-1)

cluster info (address + width)
or coincidence address (+ data)

binary FE required

comparator needed to feed trigger logic

system architectures are evolving

e.g. further ideas to combine clusters in data concentrator chip before transmission off-module, see:
<https://twiki.cern.ch/twiki/pub/CMS/SLHCTrackTriggerPrimitiveTaskForce/TriggerTaskForce14Jan09.pdf> - F.Palla 23

summary & plans

main SLHC design challenges are power and triggering

current plans for CMS strip tracker are:

binary unsparsified architecture

lose pulse height info, but retain some system features we like
should offer lowest possible FE chip power

full-size 130nm chip on first iteration – hope to submit this year
front end amplifier already under design – other parts will begin soon
specifications at preliminary stage – will develop over coming months

binary architecture already compatible with some track-trigger approaches under consideration
relative simplicity of readout scheme should allow to free-up resources to help develop
track-trigger solution (“two-in-one”, cluster-width, or stacked pixels)

=> more chips to develop

final words

time is short – chip and system design process is just the start, shouldn't forget many issues to confront:

testing – bare chips and modules

new powering schemes, SEU immunity, low temperature operation,...

assembly techniques may differ from past (wire -> bump-bonding?)

chip production: more chips than in past – longer test time and/or more test equipment/centres

has to start some years (maybe 5?) before tracker installation
